ebXML Technical Architecture Risk Assessment

ebXML Security Team
April 20, 2001

21 **1 Status of this Document**

22 This document specifies an ebXML DRAFT for the eBusiness community. Distribution
23 of this document is unlimited.

24 Note: Implementers should consult the ebXML web site for current status and revisions
25 to all specifications (<http://www.ebxml.org>).

26 ***This version:***

101 **4 Executive Overview**

102

103 We live in interesting times. The further we move toward opening our borders both in a social
 104 sense and a business sense, the more we expose ourselves to risk. E-Business technology, like
 105 any new technology reflects this environment, and risk is inevitable. But, while there may still be
 106 much security work to be done, we should recall the words of one keynote speaker at a recent
 107 security conference:

108

109 *The reason not to panic is that we have to accept the poor state of security and*
 110 *work to mitigate the risk of attacks rather than try to prevent attacks altogether --*
 111 *an impossible task.... Technology is not the enemy of security. It's only a tool, one*
 112 *that hasn't been used very well.*

113

114 ebXML is an attempt to open borders to global business. Given the limited time frame it
 115 faced, the security team decided early on that the most productive role to take would be
 116 two-fold:

- 117 • First, work with liaisons from the different working groups to discuss and identify
- 118 security issues within the working group context; and
- 119 • Second, provide an initial risk assessment of the technical architecture to identify
- 120 security issues that exist across groups or totally outside the existing group
- 121 structure.

122

123 This document is the result of that work. The effort has exposed some risks within
 124 ebXML, exactly as was the intent of the exercise. While it would have been nice to have
 125 found that ebXML is risk-free, we know this would be naive: all real systems have risks
 126 associated with them. the risks that have been identified are risks that exist in the broader
 127 internet business environment today and should be viewed in this context. To get to the
 128 point of having secure e-business, means you have to start somewhere. Classic advice in
 129 the security field is to start by securing the weakest link, then address the next link, and
 130 so on. This is the first step for ebXML: knowing how things stand. A valuable next step
 131 would be to integrate the information from the risk assessment as requirements into any
 132 ongoing activities for the respective working groups.

133

134 There are well-known security technologies that can be used by implementers of these
 135 specifications to provide a base level of security between any two ebXML partners. SSL
 136 and S/MIME are the primary candidates for providing confidentiality and authentication
 137 of endpoints. XML Digital Signatures can provide data integrity on messages, and
 138 existing authentication and authorization schemes are available to registry providers to
 139 enforce access control over data kept in the repository. Aside from XML Digital
 140 Signatures, these are the same mechanisms that are found in most web based service
 141 models today.

142

143 It is in the area of dynamic business process definition, service discovery and negotiation
144 that the bulk of the risks exist, and this can be attributed to the immaturity of the
145 technology.

146
147 Knowing where you are is often half the problem, and that's what this document tries to
148 show.

149 **5 Introduction**

150 This document describes security issues present in the ebXML technical architecture as
151 defined by the ebXML specifications listed in Section 5.3. It provides a high level
152 overview of the security issues in the relationships, interactions, and basic functionality
153 of the ebXML architectural components.

154 **5.1 Audience**

155 Security architects and implementers should use it as a roadmap to learn:

- 156 1. What risks are present in the ebXML architecture
- 157 2. What problems the ebXML security recommendations and profiles can help
158 solve; and
- 159 3. Perhaps most importantly, what security issues are yet to be addressed

160

161 **5.2 Scope**

162 The security issues raised here should be considered when reviewing the design or
163 implementation of an ebXML application. This document alone does not provide all the
164 details required to build a secure ebXML Application. Please refer to each of the ebXML
165 component specifications listed in Section 5.3 Related Documents and the related
166 reference specifications listed in the References for more details.

167 One of the difficulties in integrating security into a set of specifications that are being
168 developed in parallel is that it potentially results in additional concepts needing to be
169 addressed in a future iteration of the architecture or one of its components. In this
170 document components of the architecture are reviewed and recommendations to address
171 unresolved issues from a security perspective are identified and summarized in Section
172 15 .

173

174 **5.3 Related Documents**

175 This risk analysis considered the following ebXML Specifications on the following
176 topics:

177
178 EbXML Collaboration Protocol Profile and Agreement Specification v0.91 [ebCPP]
179 EbXML Message Service Interface Specification v 0.93[ebMS]
180 EbXML Registry and Repository Specification v0-84[ebRS]
181 EbXML Technical Architecture [ebTA]
182

183 **6 Design Objectives**

184 **6.1 Problem Description & Goals for ebXML Security**

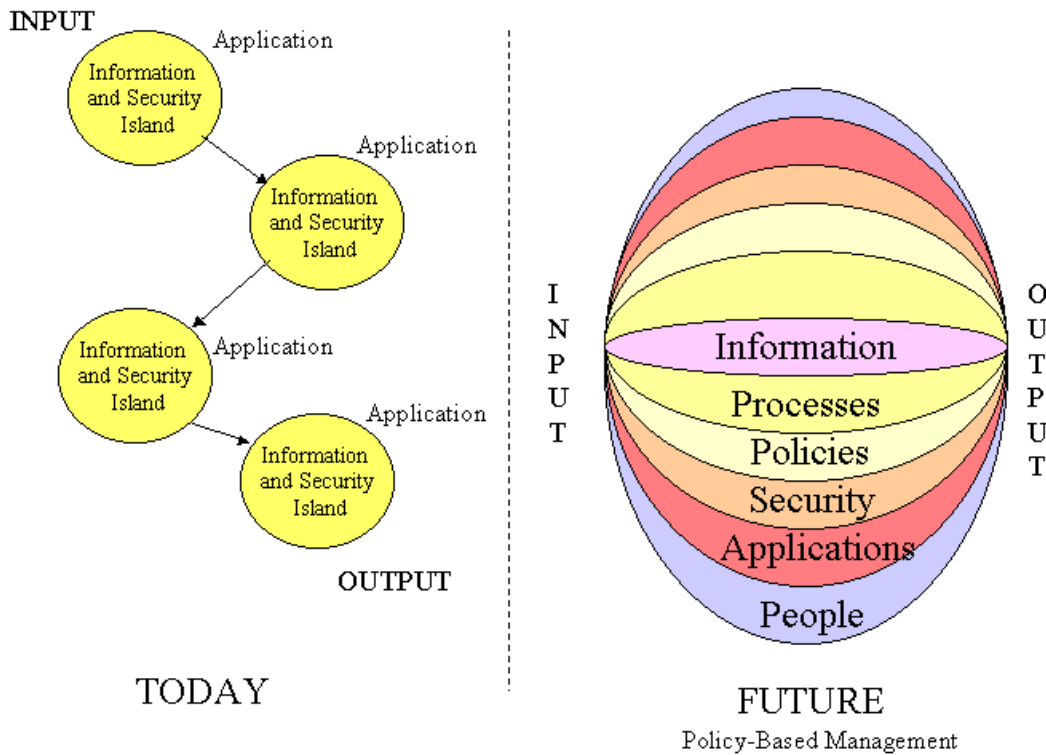

185 Implicit in business exchanges is the notion of trust. Two entities engage in a business
186 relationship with the expectation that each party will fulfill their part of their business
187 agreement. Without this fundamental understanding there could be no exchange.

188 The companies that have implemented *Electronic Data Interchange (EDI)* agreed to
189 implement common middleware that requires a significant investment to provide the
190 assurance of secure transactions. Within the overall the business world, only a small
191 percentage of companies are using EDI; consequently, common *Business Processes* are
192 dominated by paper transactions. Alternative standards in this area are emerging, but at
193 this time it is not possible to provide a complete security architecture for electronic
194 commerce based on open standards.

195 Network and system manufacturers are currently moving towards policy based
196 management partly driven by the influence of large organizations such as ISPs and ASPs
197 and partly driven by their own need to facilitate the management of large
198 implementations of networks and systems. In providing a complete risk assessment it is
199 important to consider this trend.

200 The left side of the picture below, Figure 1, attempts to illustrate how individual
201 applications today are developed in isolation and the information and security for each is
202 left within the application domain. This means that security decisions are closely tied to
203 the application and it is difficult to grow or change the security infrastructure without
204 requiring a rewrite of the application itself.

205

206
207

Figure 1 Future for Policy driven Security

208 The right side of the picture illustrates a more modular approach. In a Policy-Based
209 Management scheme, the emphasis is on building a layered infrastructure so that the
210 application can specify security requirements in terms of the business need. The entities
211 responsible for the infrastructure and management can then make the appropriate
212 decisions for mapping the application requirements into the environments security
213 capabilities and mechanisms.

214

215 This document attempts to begin a conceptual layering of ebXML applications. It
216 translates the business need for trust captured by the Business Process and Information
217 Model into a set of risk assertions that can be addressed using standard security
218 technologies. The document also identifies emerging standards that offer the potential for
219 additional levels of security in the future.

220 This document describes security for ebXML in two dimensions. First, there are security
221 technologies available that have been identified in some of the ebXML project
222 specifications (Business Process, Trading Partners, Registry & Repository, and Transport
223 Routing & Packaging). This process is similar to the isolation model. Each project is
224 addressing security within a narrow scope and demonstrating their individual piece of

225 ebXML. Second, there are security risks that need to be addressed across layers of
226 ebXML architectural components in any implementation of the ebXML architecture. In
227 the process of performing a risk assessment, this document identifies policies and
228 security layering that is the first stage in producing a policy-based architecture.

229 A set of security risks have been documented in the following Section, 7 ebXML Risks.
230 Implementers should use the references cited to provide a complete risk assessment of
231 their implementation.

232 **7 ebXML Risks**

233 Within any organization there exist vulnerabilities or risks that must be mitigated or
234 reduced to an acceptable level in order for the organization to perform business functions.
235 The following list identifies key risks for ebXML

- 236 • Unauthorized transactions and fraud – The benefit of human experience in
237 identification of unusual or inconsistent transactions is reduced with e-
238 transactions. This automation of transactions may present more risk to businesses
239 by increasing the number of opportunities to change an entity's computer records
240 and/or those of the entity's trading partners which could cause or allow fraud to
241 be perpetrated. In the automated payment generation area, the manipulation or
242 diversion of payments, payment generation in error or the inappropriate timing of
243 payments (funds not in place or payment delivered too early) are an increasing
244 risk to business.
- 245 • Loss of confidentiality – sensitive information may be inadvertently or
246 deliberately disclosed on the network. External parties might gain information
247 about transactions or specific entity knowledge without the primary party's
248 knowledge.
- 249 • Error detection (application, network/transport, system) – errors in processing and
250 communications systems may result in the transmission of incorrect trading
251 information or inaccurate reporting and. Application errors can result in
252 significant losses to trading partners and potential business losses.
- 253 • Potential loss of management and audit – There is the potential for the loss of data
254 if proper controls are not implemented. Policies for retention of data are also an
255 issue. EDI transaction data are normally maintained for long periods of time and
256 without consideration of legal and audit issues the parties may not be able to
257 provide adequate or appropriate evidence.
- 258 • Potential legal liability – the legislation for the legality of electronic transactions
259 and records are still being created. Although legal precedence has been set for the
260 use of digital signatures in the US and other countries, there are still a number of
261 countries that do not have any legislation in place for dealing with electronic
262 information. Without proven audit and control, the presentation and
263 admissibility of electronic evidence is still immature and inconsistent between
264 jurisdictions.

265 The major categories of security risks and some countermeasures for ebXML are briefly
 266 defined and then categorized in the matrix below.

| Risk Category | Risk element | Currently Available Countermeasure | Emerging Technology for Countermeasures |
|-------------------------------------|----------------------------|--|---|
| Unauthorized transactions and fraud | Identification | Biometrics (physical); electronic (userid and password, token, certificate; notarized documents | SAML[SAML] |
| | Authentication | Userid and password; PKI; token; biometrics; | SAML |
| | Authorization | RBAC; delegated; | SAML |
| | Non-repudiation of origin | XML-DSIG; PKI; paper; policies and procedures including audit and control | |
| | Non-repudiation of receipt | AS1, AS2, MDN ^{EDI} ebXML TRP persistent signed receipt plus policies and procedures | |
| | Secure timestamp | Notary; signed audit logs; | |
| Loss of Confidentiality | Application | SMIME/PGP policies and procedures including audit and control | |

^{EDI} reference needed

| Risk Category | | Risk element | Currently Available Countermeasure | Emerging Technology for Countermeasures |
|-----------------|-----------------------------|------------------------|---|---|
| | | Message | SMIME/PGP policies and procedures including audit and control | XML Encryption [XMLENC] |
| | | Transport | SSL; TLS | |
| | | | VPN | |
| | | | policies and procedures including audit and control | |
| Error Detection | Application | Virus | Anti-virus software plus policies and procedures | |
| | | Improper configuration | Configuration management; policies and procedures including audit and control | |
| | Network/ MessageLevel | Virus | Anti-virus software plus policies and procedures | |
| | | Denial of Service | | |
| | | Intrusion detection | Intrusion detection software | |
| | | Subversion | | |
| | | Protocol-level attacks | | |
| | Network/ Transport Level | Improper configuration | Configuration management; policies and procedures including audit and control | |
| | | Denial of Service | policies and procedures including audit and control | |

| Risk Category | | Risk element | Currently Available Countermeasure | Emerging Technology for Countermeasures |
|--|--------|------------------------|--|---|
| | System | Virus | Anti-virus software plus policies and procedures | |
| | | Improper configuration | policies and procedures including audit and File Access Control; Server Security; Backup and archive; CERT based safe operating practices ¹ | |
| Potential loss of Management and Audit | | Electronic evidence | policies and procedures including audit and control; backup and archival; demonstratable secure processing | WebTrust Principles and criteria for Certificate Authorities AICPA/CICA; PKI Assessment Guidelines (PAG) ABA (two guidelines for assessing and facilitating interoperability of PKIs) |
| | | Key management | policies and procedures including audit and control; CA | XKMS _{XKMS} (standard) |
| Potential Legal Liability | | | policies and procedures including audit and control | |

Figure 2 Risk Table

268

269 **8 ebXML Security Overview**

270 The business process is ultimately what defines a need for security. Security process
 271 often becomes a morass of details and technical discussion. At the root of it all is some
 272 business requirement for security, often expressed as a desire to lessen a particular risk or
 273 exposure. The current discussions on security revolve mostly around separate security
 274 mechanisms such as encryption and signing. Questions arise such as: is it necessary for
 275 confidentiality to encrypt the manifest as well as the payload? There are many such
 276 questions, and it is difficult to determine what the business process requires based on a
 277 simple desire to apply or not apply a particular security mechanism.

278 The pictures and text below attempt to capture the relationship between the security
 279 elements and the ebXML Technical Architecture components: Business Process, Trading
 280 Partners, Registry & Repository, and Transport Routing & Packaging.

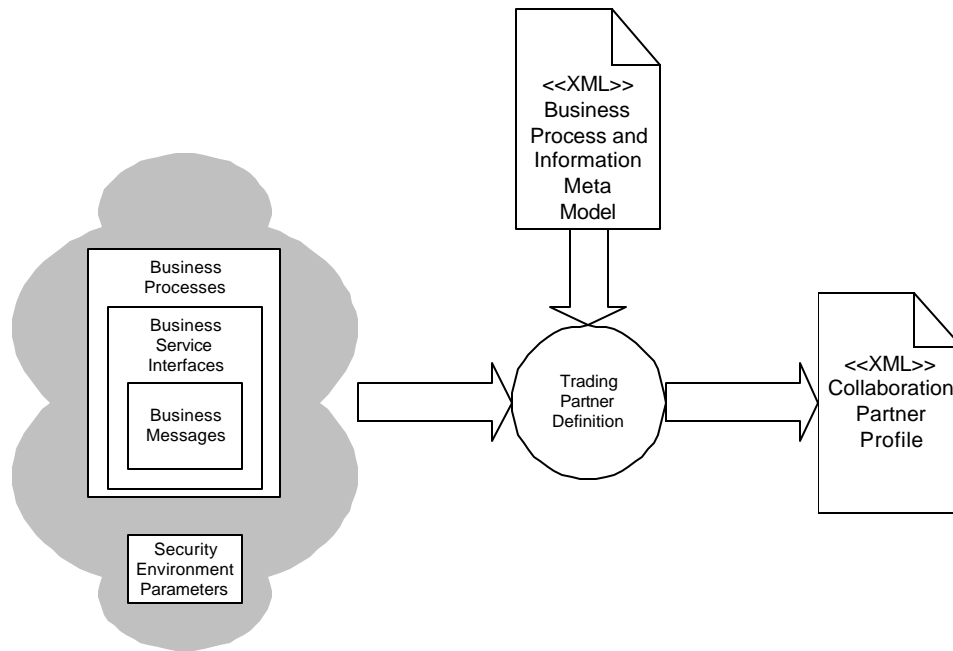

281

282

Figure 3 BP defines security characteristics

283 The Business Process (BP) definition phase attempts to capture security characteristics of
 284 a business process collaboration at a relatively high level (Figure3) . In the current
 285 ebXML flow, the information model is then “flattened” from a UML form into an XML
 286 representation and combined with other environmental information.

287
288

Figure 4 CPP is crafted from different inputs

289 The generation of the Collaboration Protocol Profile (CPP) is driven by the Business
 290 Process Information Model (and contains a reference to the model in its structure) but is
 291 not completely an automatic process. Figure 4 attempts to capture this by identifying a
 292 step called the “trading partner definition”. For the ebXML architecture to move to a
 293 policy-based architecture, it will require further work in this area to model security
 294 practices and services as well as applications. In the CPP the business requirement for
 295 providing secure transport becomes an XML element called **secureTransport**, and
 296 the business requirement for security characteristics becomes an XML attribute called
 297 **Characteristics** under the **DeliveryChannel** element as indicated in the XML
 298 fragment below.

```

299 <DeliveryChannel >
300     <Characteristics
301         nonrepudiationOfOrigin='false'
302         nonrepudiationOfReceipt='false'
303         secureTransport='true'
304         confidentiality='false'
305         authenticated='false'
306         authorized='false'
307     />
308 </DeliveryChannel>
    
```

309 This sub-element of on a **DeliveryChannel** then indicates that certain additional
 310 elements within the CPP must be defined to provide the details on how secure transport is
 311 to be provided. Following the example, if the security attribute **secureTransport** is

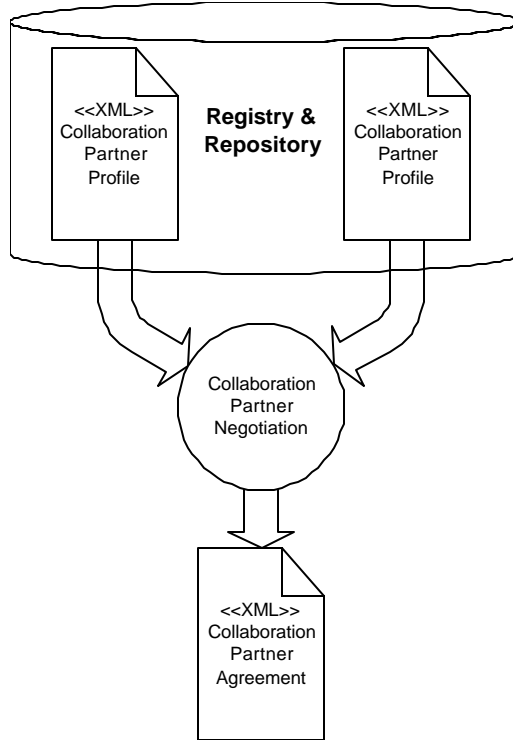

312 indicated in the CPP, then the **Transport** element of the CPP might contain details like
313 the following fragment:

```
314 <Transport transportId="N12">
315     <Protocol version="1.1">HTTP</Protocol>
316         <Endpointuri=https://www.ebxmlregisterservices.org/asynch
317             type="request"/>
318     <TransportSecurity>
319         <Protocol version="1.0">TLS</Protocol>
320         <CertificateRef certId="N05"/>
321     </TransportSecurity>
322 </Transport>
```

323 The CPP can also define different levels at which security may be present. For example,
324 the Document Exchange Section of the CPP might include tags for an *ebXML binding*.
325 An ebXML binding contains elements for describing reliable messaging and non-
326 repudiation that contains a reference to a **Certificate** structure that references the key
327 used to sign an ebXML document[XMLDSIG]². Security can also be defined at the
328 transport level (e.g. SSL via TLS). These patterns can be combined within the CPP
329 document.

330 Once a CPP has been defined, it may be stored in the ebXML compliant Registry &
331 Repository (Figure 5). When business partner A wishes to collaborate with business
332 partner B, it locates the CPP for partner B and the two parties engage in a process of
333 negotiating an agreement based on matching complimentary items in the two profiles.
334 The end result of this negotiation is a Collaboration Protocol Agreement (CPA)
335 document. Currently this is a manual process; See the following figure:

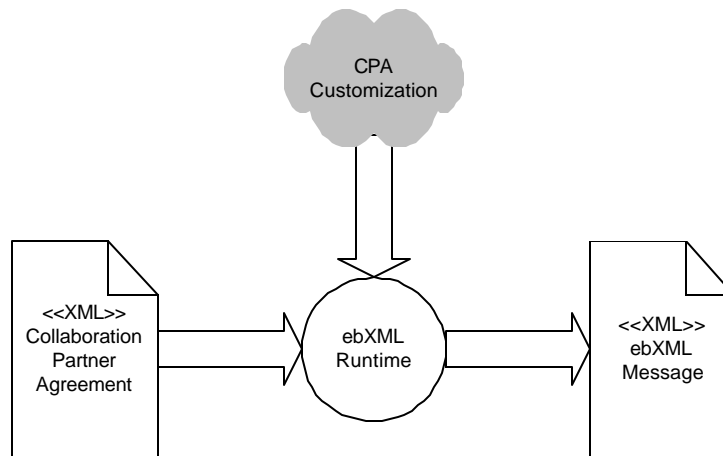

² XMLDSIG W3C XML Digital Signatures, <http://www.w3.org/TR/2000/CR-xmlsig-core-20001031/>

336
337

Figure 5 Storing a CPP and generating a CPA

338 The CPA is then used to configure the runtime for the ebXML components so that the
339 business collaboration can execute the secure business process (Figure 6).

340
341

Figure 6 Configuring the runtime

342 **9 ebXML Business Process Specification Layer**

343 The security model for ebXML relies on an assumption that the modelling of security
344 attributes at the business operational view (see the list below) is mapped appropriately to
345 the functional service view (expanded tags in the CPP).

346 The security model only addresses those security attributes that have been represented in
347 XML as a result of the conversion of business process and information models into an
348 XML representation. The current set of security characteristics that the business process
349 [ebBPSS] has chosen to represent in XML is as follows:

```
350         nonrepudiationOfOrigin  
351         nonrepudiationOfReceipt  
352         secureTransport  
353         confidentiality  
354         authenticated  
355         authorized
```

356 Currently the Business Process asserts security characteristics at a very coarse level. An
357 example of this coarse granularity is given in the paragraphs below in the description of
358 the issues surrounding *non-repudiation*.

359 To provide end-to-end security it must be possible to assert security requirements at a
360 finer level of granularity in the business information model. For example, there are a
361 number of things within the business model to which security characteristics can be
362 applied, for example documents, delivery channels, or business processes as a whole.

363 This cannot be done with the current level of detail. The coarser the granularity of the
364 security characteristics, the simpler but more limited the options are. In the beginning of
365 any such effort, it is natural to start with the simple, coarse-grained security
366 characteristics. However, eventually the business process will require finer granularity to
367 the security characteristics despite the challenging nature of such added detail .

368 For example, it is difficult with the current set of security characteristics to indicate
369 whether *non-repudiation* is handled by the application or by the message service layer. It
370 is also difficult to see how this is represented by the CPP. To assert that non-repudiation
371 of receipt is addressed means that some pieces of the message header and payload are
372 being asserted as evidence. In addition, a hash has been generated over this information
373 and evidence that the receiver is able to verify that same hash value is returned in the
374 acknowledgement of receipt to the sender. The sender then needs to archive this
375 information as evidence.

376 Currently each party defining a BP must choose to apply or not apply each security
377 mechanism at each level separately. This leads to a complex representation within a CPP
378 and a potential problem with an increased risk of improper configuration at the packaging
379 stage where it must be decided which parts of the message security should be applied to.

380 To bootstrap the ebXML process, a set of profiles that represent typical business
381 requirements must be established. If additional scenarios are identified, new profiles
382 could be created/documented and added to the choices for parties defining BP. Sample
383 profiles could address particular business needs, and define those security services
384 necessary to meet those needs. A good example profile would be one for non-repudiation
385 of receipt (NRR). The business process might require that the sending party receive solid

386 proof that the receiving party received the payloads unaltered. If NRR is desired, signing
387 will almost always be required as well. In addition it is most likely only necessary to sign
388 the payloads, and generate the NRR response over the payloads. A profile could be
389 created for this scenario, and the party generating the BP could simply choose to apply
390 this profile rather than having to choose a more complex and obtuse set of security
391 settings. In Appendix B Packaging Profiles there are four sample profiles for secure
392 packaging of the application payload:

- 393 • Application encryption over payload using PGP [PGP]
- 394 • Application encryption over payload using S/MIME [SMIMEV2][SMIMEV3]
- 395 • Application signing over payload using PGP [pgp]
- 396 • Application signing over payload using S/MIME

397 **10 Trading Partner Information**

398

399 In order to reduce risk to an acceptable level, potential trading partners must be able to
400 authenticate each other's identity, verify the integrity of the messages they exchange, and
401 ensure the confidentiality of those messages as they transit the network (known
402 collectively as an ebXML security policy). The degree to which they will want to do
403 these things will vary greatly depending on the situation.

404

405 There are many factors that can affect the ability to accomplish the desired level of trust.
406 These include the following:

407

- 408 • Some nations regulate the export, import, or use of cryptographic software. The
409 only means to address this is to ensure that algorithms, key sizes etc are always
410 identified
- 411 • Most cryptographic protocols actually support a suite of algorithms and data
412 structures (known collectively as mechanisms). So, even if both parties use
413 XMLDSIG, partners will not be able to validate and verify a signature if one uses
414 X.509 [PKIX]mechanisms while the other only uses PGP. A potential way to
415 address this is by defining some base-level profiles that all implementations
416 support to identify which mechanisms a party uses so that “common operating
417 dialects” can be found.
- 418 • Even when using common mechanisms, proper interpretation of authentication
419 data can be very difficult and error-prone. For example, even after years of
420 standardization, correct specification of how to validate X.509 certificate paths
421 proves elusive. Given the current state of PKIX [PKIX]development, deferring to
422 the manual evaluation step in CPP/CPA negotiation may be the only appropriate
423 action for agreeing to a certificate validation scheme.
- 424
- 425

- 426
- 427
- 428
- 429
- 430
- 431
- 432
- 433
- 434
- 435
- 436
- 437
- 438
- 439
- 440
- 441
- Important pieces of a complete on-line solution are not widely deployed or even specified. For example, determining if a partner's certificate has been revoked, or if they are authorized to make purchases, can only be solved –if at all—through a series of ad hoc methods. This technology will evolve but again, manual evaluation is the only practical option for establishing revocation policies at this time.
 - This document proposes that a trust anchor element be created within the CPP and that it be represented as an XML Digital Signature[XMLDSIG] *KeyInfo* element. It is an endpoint for a set of credentials used by the party. It is important to recognize that a single policy will probably have multiple anchors. For example, a small enterprise might have an SSL certificate from a DNS registrar, yet use PGP[PGP] keys signed by a particular staff member for all purchasing agents.

442 In spite of these factors, it is still possible to create a secure association between trading
443 partners, and automate a large portion of the establishment of that association by defining
444 a **SecurityPolicy** element in the CPP. This element would advertise the set of security
445 mechanisms a party understands, the profiles for those mechanisms, and the trust anchors
446 that will be issuing the credentials used within that policy. The policies can be
447 asymmetric, allowing separate identification of what it can accept from what it will,
448 itself, generate. For example, a party might accept SSL-protected messages, but will
449 itself, only generate [XMLDSIG] signed acknowledgements.

450

451 In order to encourage maximum interoperability, the following standard mechanisms are
452 identified and vendors are encouraged to implement them:

- 453 -
- 454 ▪ When exchanging identity information, use X.509v3 Certificates that following
455 the IETF profile (RFC2459 and its successors) [PKIX]
 - 456 ▪ When symmetric-key encryption is needed, use 3DES or the AES.
 - 457 ▪ When asymmetric encryption is needed, use RSA encryption with the OAEP
458 encryption scheme and a key size of 1024 or 2048 bits.
 - 459 ▪ When hashing (or digesting) is needed, use SHA-1
 - 460 ▪ When transport-level security is required, use SSLv3 or TLS with RSA keys and
461 the RC4 (or ARC4) stream cipher.

462

463 The intent of this document is to initially establish the profile above as a text reference
464 and identify it by the URN *urn:security.ebxml.org/profiles/baseline*. Future versions of
465 the ebXML standards may provide detailed profiles as the correct format for this
466 information and its relationship to the CPP elements are further refined.

467

468 **10.1 PKI Interoperability Issues**

469

470 A Public Key Infrastructure is more than just technology. In fact, technical
471 interoperability accounts for about 20% of the issues when organizations want to cross
472 certify or otherwise trust each other's certificates. There are a number of business,
473 policy, procedure, audit and control issues that must be addressed prior to cross
474 certification. This type of information should be covered in the CPA. Some of the key
475 issues are covered below.

476

- 477 • Legal issues – for dispute resolution there may be a requirement to resolve
478 the dispute in court and it should be determined up front what laws apply
479 and in what jurisdiction.
- 480 • Liability issues – who accepts liability, when and how much should be
481 determined (usually per transaction but could be daily or some other means
482 that meets both parties' needs)
- 483 • Level of assurance – in determining the limit of liability, the level of
484 assurance (the level of assurance is based on the level of risk associated
485 with identification, authentication, authorization and security of a
486 certificate) must be determined for each organization and the proof of
487 compliance to that level (compliance audit performed)
- 488 • Cultural and political issues – when dealing with entities external to an
489 entity's borders there may be different cultural or political issues that must
490 be addressed
- 491 • Policies and procedures (see level of assurance) there is a need to
492 determine how certificates are managed such as revocation and timely
493 posting to CRLs and/or OCSP responder, what applications are enabled,
494 how they are enabled, key escrow (NOTE private signing keys should NOT
495 be escrowed) etc.
- 496 • Technical – key size, certificate extensions, algorithms used, physical
497 controls, key usage periods, private key protection, etc.

498

499 Appendix C documents a sample XML fragment for defining CPP elements related to
500 public key policies.

501 **10.2 CPP/CPA Security Elements**

502

503 In the current version of the CPP/CPA , the specification of security elements is limited.
504 It is recommended that XML schema be considered to more effectively express security
505 attributes. For example, the security characteristic is a single element that contains
506 attributes with Boolean values indicating whether or not a security attribute has been
507 addressed. It would be useful to have the security characteristics have a type and be
508 able to have a reference id to include on lower elements (like the transport element)
509 which contain the details like the protocol.

510

511 In addition, it is entirely feasible to develop a super schema that would combine a
512 description of the CPP with description of the CPA and correlate the relevant components
513 of the two using the key/keyref mechanism of XML schema. This would allow a contract

514 validator to match the correlated components to make sure that the contract is actually
515 met.

516

517 The current CPP/CPA does not contain all the details needed to express both the policy
518 and the operational details for specifying security. It is important that any ebXML follow
519 on activity consider creating a group of participants from Business Process, Trading
520 Partners, Security and TR& P to evolve the security attributes currently specified in the
521 CPP.

522

523 It is unclear from the current analysis, where new elements should be attached within the
524 CPP. Two options considered are to attach them to a delivery channel or to attach them
525 to the service binding element of the CPP. If the details are attached to a delivery
526 channel the entire document must be parsed in order to look for matching security
527 attributes. If the details are attached to the service binding, it is easier to relate the
528 security attributes with the packaging elements currently specified in the service binding.
529 In addition to additional policy elements, some iteration through the CPP might also
530 allow Trust Anchor elements to be grouped like Certificate elements and allow the
531 channel specifications to reference the id of a trust anchor subset.

532

```
533     <SecurityPolicy>
534       <TrustAnchors>
535         <!-- a set of <ds:KeyInfo> elements. -->
536         <ds:KeyInfo ID='foo'>...</ds:KeyInfo>
537         <ds:KeyInfo ID='bar'>...</ds:KeyInfo>
538         <ds:KeyInfo ID='chumley'>...</ds:KeyInfo>
539       </TrustAnchors>
540       <Profiles>
541         <!-- A set of "Profile" elements. Each profile
542              identifies a profile, and then the anchors
543              used in that profile. -->
544         <Profile ID="pf1" URN="urn" ANCHORS="foo bar"/>
545       </Profiles>
546       <WillUse>
547         <!-- A set of profiles the party will use. -->
548         <ProfileRef>pf1</ProfileRef>
549       </WillUse>
550       <WillAccept>
551         <!-- A set of profiles the party will accept. -->
552         <ProfileRef>pf1</ProfileRef>
553       </WillAccept>
554     </SecurityPolicy>
```

555

556 To address the secure packaging part of the Transport Routing & Packaging
557 configuration in the CPP, the CPP should also document the packaging of the message
558 header, payload and attachments so that S/MIME or XMLDSIG can be used to protect
559 the appropriate elements of the message. If the packaging is well defined, it will allow
560 the security tags within the CPP to specify the appropriate certificate data (X.509, PGP,
561 etc.) to be applied to securely sign/encrypt the elements of the Message. This new

562 Packaging Element in the CPP has been proposed, but it needs to be reviewed and an
563 assessment made of whether it addresses this requirement
564

565 **11 Registry and Repository**

566 From a security perspective, the Registry service of ebXML can be seen as a specific case
567 of an ebXML transaction. It is possible to model its operations according to the ebXML
568 Specification Schema and an appropriate CPP in the same way any other application
569 would specify security and requires no additional security infrastructure.

570 **11.1 Registry**

571 A security proposal for the Registry and Repository (R&R) is documented in [REGREP].
572 The Registry workgroup within ebXML currently indicates that this activity will likely
573 not complete within ebXML's lifecycle

574 The following scenario illustrates how security for Registry processes *might* be
575 specified. Note the following paragraphs and Appendix D (Registry Sample) documents
576 an exercise to explore how an application might define its Business processes and
577 messages as a way of illustrating the process of defining security for any ebXML
578 application. The Registry group is encouraged to engage in such an exercise upon
579 completion of their specification and to add to the profiles defined by the security group.

580 For the purposes of this exercise, the parties identified are the **Registry Guest**, the
581 **Content owner of Submitting organization** and the **Registry Service**. The **Content**
582 **owner of Submitting organization** wishes to register its business information in the
583 ebXML Registry and Repository. The Content Owner evaluates the CPP in the Registry,
584 which describes how a document can be submitted. It then creates and signs an ebXML
585 document containing this business information and constructs a message
586 (`RegistrySubmitManagedObject`) to send to the Registry Service.

587 The **Registry Authority** receives the registration request (via an XML document in a
588 TRP message envelope)

589

590 Any **Registry Guest** is able to read all business entries.

591

592 In Appendix D there is a skeletal CPP. In the CPP, the role of “content owner” is
593 defined and a reference is made to an external document which contains the Process
594 Specification Document for ebXML Registry & Repository. A content owner who wants
595 to add a CPP document to the Registry, creates a CPP document, signs it and sends it to
596 the Registry. Because the Registry needs to know who is responsible for the document,
597 the connection to the registry must be authenticated.

598

599 A second CPP is included which identifies the role of “registry guest”. Requests for
600 information from a registry are public requests. There is no security required for the
601 connection to the registry in this instance.

602 **11.2 Repository**

603 Security for the repository is currently the responsibility of the implementer. This is an
604 appropriate security choice, but it may have implications for authorization of access to
605 the registry and any additional requirements for authorization should be included in the
606 Registry & Repository business process definition. It is suggested that a note to
607 implementers recommends that the security for the repository be documented and that a
608 risk assessment for the interface between the registry and the repository is performed.

609 **12 Messaging Service Functionality**

610
611 The initial assessment of the Message Service was done on the December version of the
612 document and within the TRP document security issues are well documented and
613 addressed primarily in Section 12. The latest TRP specification V0.98 includes a
614 merging of ebXML messaging and the SOAP messaging model and an initial assessment
615 has been made of this new model. . There are several topics some of which are not
616 specifically related to security mechanisms that are identified here as topics to consider
617 in future ebXML activity related to secure reliable messaging.. .

618 **12.1 SOAP-SEC extensions and Signatures in ebXML Messages**

619
620 Given that an ebXML message is carried within a SOAP message, there are two ways
621 currently of signing messages and this may cause some confusion or runtime failures due
622 to misinterpretation. There has been a note posted to the W3C which identifies one
623 possible set of processing instructions for signing SOAP messages. Below are some
624 "similarities and differences" that may help people wade through the notations. In
625 addition, there is a good reminder in the concluding section of the XMLDSIG note about
626 digital signature not itself preventing replay attacks. The "no-dupes" of reliable
627 messaging can be used to address this type of attack.

628

629

630 1. SOAP-SEC uses its own namespace and has a schema that wraps around
631 the XMLDSIG namespace, unlike the ebXML example.

632

633 2. SOAP-SEC and ebXML Digital Signatures both have the signature under the SOAP-
634 ENV:Header.

635

636 3. The SOAP-SEC schema allows just one signature

637

638 4. SOAP-SEC uses the SOAP-ENV:actor and SOAP-ENV:mustUnderstand elements,
639 whereas the ebXML exaple does not.

640

- 641 5. The actual W3C XMLDSIG machinery is shared. Of course, the ebXML example
642 illustrates using an XPATH transform to cut out the TraceHeaderList (though the S1
643 value
644 for the id attribute doesn't point to anything in the ebxml example...)
645
- 646 6. The ebXML-Sig Reference mechanism uses cid: style URIs, but these are also
647 acceptable in SOAP-SEC (section 3.2
648
- 649 7. SOAP-SEC uses the soap protocol conventions of the mustUnderstand and actor
650 constructs. It is not certain whether this is an advantage or just overhead. It might be a
651 disadvantage if SOAP processing and ebXML MSH processing are "walled-off". In that
652 case, no defined lines of communication to the MSH from the SOAP layer exist so that
653 MSH won't have access to the outcomes of checking. In general, it is difficult to assess
654 the impact on implementations, but using SOAP-SEC within ebXML would tend to
655 promote writing a SOAP processing layer as part of the MSH to facilitate
656 communication.

657

658 **12.2 Lack of Processing Rules**

659

660 The TRP document addresses wire format only. Given the complex nature of composing
661 a message that adequately reflects both security and reliability in addition to the correct
662 business process data, there is a good deal of the processing of a business message
663 through the MSH to the SOAP process that is left as an exercise for the reader. While the
664 TRP specification makes a recommendation on how signatures should be applied to a
665 message envelope, there are still areas of overlap between the SOAP envelope and the
666 ebXML envelope that probably need further definition. As is mentioned in Section 11.1
667 item 7, there is no defined line of communication to the MSH from the SOAP layer.
668 There are several areas in which the specification of the sequence of processing of a
669 message would be helpful.

670

671 Intermediaries and the processing of "via" elements in TRP and SOAP actors with
672 mustUnderstand attributes is one area in which there is a risk of runtime failures if the
673 message flow from both the SOAP processor and the ebXML processing agent is not
674 well understood by all parties.

675

676 There are several other areas of processing that are just general areas of caution due to the
677 relative immaturity of XML technology. Transformations are one such area of concern.
678 TRP signing identifies style sheet transforms (as does the XMLDSIG specification) as of
679 particular concern due to the inconsistency of output from different implementations. In
680 particular caution should be used when data from a signed message is parsed and
681 validated and then the data is to be included in another signed message. The data should
682 be re-signed rather than attempting to pickup a signed piece of information within one
683 message and appending it to another message. The technology to perform consistent
684 transformations is something that will evolve over time. The addition of XML encryption

685 in combination with XML Digital signatures will possibly make this even more complex
686 before it becomes more consistent.

687

688

689 **12.3 Manifests**

690 Independently and collectively, SOAP (with and without attachments), XML digital
691 signatures (and, prospectively, XML encryption) and ebXML offer multiple mechanisms
692 for component reference. Most notable among these is the "manifest". These reference
693 mechanisms allow the composition of macroscopic message structures from microscopic
694 message components. Similarly, SOAP and ebXML each offers a way of routing
695 messages through intermediaries: the "actor" attribute in the case of SOAP and "via"
696 element in the case of ebXML. These routing mechanisms can be thought of as a way of
697 constructing processes on messages and this can be done dynamically.

698

699 Any design environment offering multiple ways of accomplishing the same end
700 challenges the application developer with choices that often seem unmotivated, hence
701 difficult to explain. (The existence of the—largely interchangeable--attribute and element
702 constructions in XML itself are a good example.) This greatly increases the likelihood of
703 error. The deeper concern, however, is how these compositional mechanisms interact. As
704 there are neither syntactic nor semantic constraints on the interleaving of these
705 functionally similar features, it is probably wise to anticipate that there will be unpleasant
706 system surprises, especially when independent developers make use of composability.
707 While our concern is a generic one, it comes vividly into focus when combining security
708 with messaging.

709

710 A case in point is a scenario in which a SOAP-encoded ebXML message mentions "vias"
711 V1 and V2. Suppose further that the SOAP envelope mentions "actors" A1 and A2. The
712 designers' intention is that V1 signs the ebXML message and V2 does signature
713 validation. On the other hand the SOAP server has been configured to direct all traffic
714 through, A1 which encrypts while A2 decrypts. This means that A2 needs to process the
715 decryption before V2 is readable. In this case, what if A2 does not know about V2? The
716 "ebXML" process thought the message would go from V1 to V2 and was unaware of the
717 outer routing. And this is a simple case. On the face of it, there seems to be nothing to
718 prevent routing episodes in which attempted signing, encryption, validation and
719 decryption may fail.

720 **12.4 Key Management**

721 Key management is a major issue that needs to be addressed with respect to the
722 capabilities of the TR& P Message Service Handler. In particular, if the MSH will be
723 called upon to apply digital signatures, the appropriate private keys must be available to
724 the MSH. Private keys must be managed very carefully and deliberately. Thus, some
725 configuration will be necessary to establish the key management mechanisms to be used
726 by the MSH.

727 **13 Conformance**

728 **13.1 Overview**

729 Conformance will be based on adhering to the specific conformance requirements
730 delineated in the ebTA, ebRS, ebMS, ebBPSS and ebCPP specifications.

731 **13.2 Conformance Requirements**

732 Types of conformance requirements can be classified as:

- 733 a) Mandatory requirements: these are to be observed in all cases;
734
735 b) Conditional requirements: these are to be observed if certain conditions set out in
736 the specification apply;
737
738 c) Optional requirements: these can be selected to suit the implementation, provided
739 that any requirement applicable to the option is observed.

740 Furthermore, conformance requirements in a specification can be stated:

- 741 • Positively: they state what shall be done;
742 • Negatively (prohibitions): they state what shall not be done.
743

744 **14 Future Requirements**

745 **14.1 Multi-hop and third party security services**

746 The ability to simultaneously support multi-hop traceability and message integrity
747 validation is an issue that must be addressed. For message integrity validation, it is
748 desirable to apply a digital signature to of as much of the message as possible. To support
749 multi-hop traceability, each intermediary must add a new section of signed traceability
750 information. Care must be taken to establish message structuring and processing that
751 allows the traceability information to be added without disturbing any preexisting
752 integrity or traceability components. With this in mind, it is constructive to consider the
753 proposed ebXML message structure (shown below) in conjunction with potential security
754 mechanisms.

755
756

Figure 7 ebXML message structure

757 There have been discussions of applying S/MIME security mechanisms to the entire
758 message (in the previous figure, this would include the elements grouped under the
759 MIME multipart/related label).

760

761 The move to using an underlying SOAP message envelope may require the restructuring
762 of the current CPP definition of the “nonrepudiation” element and its sub elements. The
763 current tag specifies a protocol and hash algorithm but does not adequately express how
764 this can be applied to an ebXML message (either parts or the complete message) to
765 provide evidence that the receiver has adequately verified the receipt of a signed message
766 and replied with a receipt acknowledging the same hash value over the signed message.

767 **14.2 Archiving**

768 The mechanisms for storing Business Process Information Models, Collaborative Partner
769 Profiles and other related business information should supply assurances that the
770 information stored and retrieved has not been modified by an unauthorized entity. The
771 requirements state that the information should be able to be reconstructed at some point
772 in the future, and at present it is difficult to know if this requirement has been met by the
773 registry security proposal.

774 **14.3 Minimum Security**

775 It is currently assumed that the collaboration agreement (CPA) reached between two
776 Trading Partners adequately reflects the ordering and priority of security policies stated in

777 the CPP, but there is no mechanism for establishing minimum security requirements.
778 The current CPP DTD does not allow the tagging of security configuration at a level that
779 indicates what is required, what is optional, or what is preferred. There is not sufficient
780 detail regarding properties like geography or liability (financial as well as legal) that
781 might affect the choice of security mechanisms in an automated negotiation process.

782 Describing business' capabilities may misrepresent the intent of the CPP.

783 **14.4 Automated CPA Generation**

784 Within the Trading Partner group there is discussion about the dynamic generation of a
785 CPA. The resolution of the CPA generation may require an additional version of this
786 document to address the security issues in CPA negotiation, but it is currently out of
787 scope.

788 **14.5 Issues for non-repudiation of receipt (NRR)**

789 (NOTE: This discussion focuses on message level NRR. Application level responses are
790 out of the scope of this discussion).

791 From a top level (business level) perspective, the most important issue is to determine
792 exactly what parts of the message are subject to NRR. For example, should NRR be
793 applied to the payload items and/or the header? One suggested solution would be to apply
794 NRR to only those parts of the message that were signed by the originator.

795 The next issue is what how the NRR response should be sent back to the message
796 originator. Should the message be sent back as part of another ebXML message, or
797 should a separate mechanism be used (such as AS1 and/or AS2).

798 The third and final issue is determining what format the NRR response should take. If it
799 is chosen to use an externally defined transport and format such as AS1 or AS2, then this
800 decision is already made. If however ebXML is the chosen transport, it needs to be
801 decided where the NRR response should reside (in the SOAP header, or body, etc.).
802 Additionally, it needs to be decided what that NRR should contain. It has been proposed
803 within the TRP group that a NRR response should simply be the acknowledgements
804 element which has been signed, but that neglects to include a hash of the parts of the
805 original document for which the NRR is being generated. At a minimum, the hash of the
806 original message parts and a reference to those parts (such as the acknowledgements
807 element) must be signed to supply NRR. As part of the format used, there must be a
808 decision made about what algorithms and transformations will be used to sign the NRR
809 response.

810 Once all of those issues have been decided, there must be some mechanism within the
811 CPP for any optional information (such as the scope of the desired NRR) to be supplied.

812 14.6 Registry and Repository Authentication

813 In selecting distinguished names as the binding mechanism to a key, the risk is run that
814 other non X.509 key binding schemes are ignored. (Ref: 9.2) A more generic alternative
815 mechanism is recommended for mapping from keying material to a unique identifier
816 within the registry. A registration process to associate the keying material with the
817 implementation identity would allow for support for more alternative key binding
818 schemes. (For further reading please see section 9.1 first paragraph of the R&R spec).

819 14.7 Messaging without a CPA

820

821 There has been discussion on the TRP mailing list including participants from TP and
822 Security around the topic of CPPs and CPAs and whether they are required for
823 Messaging. The risk analysis provided in the overview of this document is dependent
824 upon an agreement between two trading partners being reflected in the creation of a
825 CPA document. It is recommended that a CPA be signed by both parties to indicate
826 their commitment to the agreement.

827

828 The TRP spec currently requires a CPAId element (a string that identifies the parameters
829 that control the exchange of messages between the parties) in a message exchange.

830 Businesses who engage in transactions without documenting their agreement should be
831 aware that all assurance that the business process was adhered to is outside of the
832 ebXML architecture and must be agreed upon and substantiated by some other means.

833

834

835 **15 Additional Requirements and Recommendations**

836

837 **Registry & Repository**

838

- 839 • A more generic alternative mechanism is recommended for mapping from keying
840 material to a unique identifier within the registry
- 841 • It is recommended that implementers of a repository perform a risk assessment for
842 the interface between the registry and the repository .

843

844 **CPP/CPA**

845

- 846 • Additional policy based elements need to be added to the CPP and several
847 suggestions are included in this document
- 848 • A stronger use of schema to type security could aid in the automatic generation of
849 CPAs
- 850 • Defining a set of common profiles would greatly improve chances for interoperability
- 851 • The coarse grained nature of the security characteristics element may increase the risk
852 of improper security configuration. Manual review of the CPA is recommended .

853

854 **Business Process**

855

- 856 • Modeling of the business process should include a finer grained expression of
857 security characteristics. The current set greatly limits the ability to represent security
858 throughout the creation and transport of the business content.

859

860 **Transport Routing and Packaging**

861

- 862 • The absence of processing rules for message composition in particular, with regard to
863 security in messages, may increase the risk of runtime failure due to
864 misunderstanding of the ordering of actions to successfully decompose the message.
- 865 • The absence of a clearly defined handoff between SOAP and ebXML and the
866 existence of “intermediaries” at both the SOAP and ebXML level may increase the
867 risk of runtime failures.

892 Appendix A. Security Assertion Markup Language (SAML) ebXML use case

893 The Oasis Security Services Technical Committee is in the process of developing a set of
894 requirements and use cases to develop a language for security assertions. The following
895 use case has been submitted as a generalized use case for ebXML applications that
896 require authentication and authorization. It is based on the work done by the security and
897 registry groups in an exercise to develop a POC example for a business process that
898 required authorization. The use case was submitted to the SAML group so that some
899 ebXML application requirements would be considered in the specification that the SAML
900 group will produce.

901 When the specification is issued, its use within ebXML will need to be explored and
902 documented. Additional elements might be required in the CPP to provide the appropriate
903 information about authorization and authentication authorities and parameters of the
904 assertions.

905 The submitted ebXML use case was grouped with others in the “business to business”
906 scenario.

907 Scenario 1: General Use cases for ebXML authorization

- 908 1) Party A wishes to engage with Party B in a business transaction. To do this, Party A
909 accesses information stored in an ebXML CPP about Party B’s requirements for
910 doing business. Some of this information might include:
 - 911 a. Party B requires authorization credentials from AuthorizationServiceXyz
 - 912 b. Party B requires that Party A be authorized by XYZ in the BuyerQ role.
- 913 2) Party A then must be able to determine:
 - 914 a. How to get these authorization credentials
 - 915 b. Where/how to insert these credentials in an ebXML message (need to define
916 ebXML bindings)
- 917 3) Party B has received a digitally signed ebXML message from party A and wishes to
918 obtain authorization information about party A
 - 919 a. Authorization data must be retrievable based on the DN in the certificate used
920 to sign the ebXML message
- 921 4) Party A has enrolled with AuthorizationServiceXYZ. Party A engages in ebXML
922 business transactions and wants to restrict what entities are able to retrieve its
923 authorization data.
